

On-site indoor scan planning for building hull investigation

Task

Resource-efficient and automated building surveilling can support planners in scaling their renovation projects across the existent building stock. Commonly, an inventory is made with thermal infrared imagery (TIR) and mostly manual geometric measures. In this project a quantitative and automated workflow will be built to identify thermal anomalies in the building-hull from the outside, reference them to the 3D geometry[1] and plan the further investigation by scanning from inside the building.

The students will be guided through the following tasks:

- *Outdoor data acquisition (LiDAR scan and TIR images)*
- *Thermal anomaly detection with (ML) image segmentation methods*
- *Temperature information projection onto the geometric point cloud*
- *Matching of the acquisition data with building plans / models (BIM)*
- *Identify sensible indoor scan positions for more detailed investigation*
- *Conduct indoor surveilling*

Special focus will be on the on-site-usability of the solution.
